

Machine Learning

Naïve Bayes Classifier

Probability Basics

Consider Problem of tossing two coins. The sample space as

$\{HH, HT, TH, TT\}$

Some of the probabilities in this experiment would be as follows:

The probability of getting two heads

$$= 1/4$$

The probability of at least one tail

$$= 3/4$$

The prob. of the second coin being head given the first coin is tail

$$= 1/2$$

Bayes Theorem

- Let us apply Bayes theorem to our coin example. $S=\{HH, HT, TH, TT\}$

Let A be the event that the second coin is head, and B be the event that the first coin is tails.

- Probability of A given B:

$$P(A|B) = [P(B|A) * P(A)] / P(B)$$

$$= [P(\text{First coin being tail given the second coin is the head}) * P(\text{Second coin being head})] / P(\text{First coin being tail})$$

$$= [(1/2) * (1/2)] / (1/2)$$

$$= 1/2 = 0.5$$

- Bayes theorem calculates the conditional probability of the occurrence of an event based on prior knowledge of conditions that might be related to the event.

Bayes Theorem

The Bayes theorem gives us the conditional probability of event A, given that event B has occurred.

$$P(A | B) = \frac{P(B | A)P(A)}{P(B)}$$

where:

$P(A|B)$ = Conditional Probability of A given B

$P(B|A)$ = Conditional Probability of A given B

$P(A)$ = Probability of event A

$P(B)$ = Probability of event A

Bayes Theorem

$$P(A | B) = \frac{P(B | A) P(A)}{P(B)}$$

Joint Probability

$$P(A | B) = \frac{P(A \cap B)}{P(B)}$$

Conditional Probability

Likelihood

Class Prior

$$P(A | B) = \frac{P(B | A) P(A)}{P(B)}$$

Posterior Probability

Predictor Prior

Bayes Theorem

Bayes Theorem

- In a factory there are 100 units of a certain product, 5 of which are defective. We pick three units from the 100 units at random. What is the probability that none of them are defective?

Bayes Theorem

- Let us define A_i , $i=1,2,3$ as the event that the i th chosen unit is not defective.

We are interested in $P(A_1 \cap A_2 \cap A_3)$.

Note that $P(A_1)=95/100$.

- Given that the first chosen item was good, the second item will be chosen from 94 good units and 5 defective units,

thus $P(A_2|A_1)=94/99$.

- Given that the first and second chosen items were okay, the third item will be chosen from 93 good units and 5 defective units,

thus $P(A_3|A_2, A_1)=93/98$.

- Thus, we have

$$P(A_1 \cap A_2 \cap A_3) = P(A_1)P(A_2|A_1)P(A_3|A_2, A_1) = 95/100 * 94/99 * 93/98 = 0.8560$$

Example 4.14. An urn has 5 blue balls and 8 red balls. Each ball that is selected is returned to the urn along with an additional ball of the same color. Suppose that 3 balls are drawn in this way.

(a) What is the probability that the three balls are blue?

Solution: In this case, we can define the sequence of events B_1, B_2, B_3, \dots , where B_i is the event that *the i th ball drawn is blue*. Applying the multiplication rule yields

$$\mathbb{P}(B_1 \cap B_2 \cap B_3) = \mathbb{P}(B_1)\mathbb{P}(B_2 \mid B_1)\mathbb{P}(B_3 \mid B_1 \cap B_2) = \frac{5}{13} \frac{6}{14} \frac{7}{15}.$$

Chain rule for conditional probability:

$$\begin{aligned}\mathbb{P}(A_1 \cap A_2 \cap A_3 \cap A_4) &= \mathbb{P}((A_1 \cap A_2 \cap A_3) \cap A_4) && [\text{treat } A_1 \cap A_2 \cap A_3 \text{ as one event}] \\ &= \mathbb{P}(A_1 \cap A_2 \cap A_3) \mathbb{P}(A_4 \mid A_1 \cap A_2 \cap A_3) && [\mathbb{P}(A \cap B) = \mathbb{P}(A) \mathbb{P}(B \mid A)] \\ &= \mathbb{P}((A_1 \cap A_2) \cap A_3) \mathbb{P}(A_4 \mid A_1 \cap A_2 \cap A_3) && [\text{treat } A_1 \cap A_2 \text{ as one event}] \\ &= \mathbb{P}(A_1 \cap A_2) \mathbb{P}(A_3 \mid A_1 \cap A_2) \mathbb{P}(A_4 \mid A_1 \cap A_2 \cap A_3) && [\mathbb{P}(A \cap B) = \mathbb{P}(A) \mathbb{P}(B \mid A)] \\ &= \mathbb{P}(A_1) \mathbb{P}(A_2 \mid A_1) \mathbb{P}(A_3 \mid A_1 \cap A_2) \mathbb{P}(A_4 \mid A_1 \cap A_2 \cap A_3) && [\mathbb{P}(A \cap B) = \mathbb{P}(A) \mathbb{P}(B \mid A)]\end{aligned}$$

Assume that we have two classes:

c_1 =male and c_2 =female

We have a person whose gender, we
Do not know, say “drew” or d

Classifying *drew* as male or female is
equivalent to asking is it more probable
that *drew* is male or female, ie. Which is
greater $p(\text{male}|\text{drew})$ or $p(\text{female}|\text{drew})$

(Note: “Drew
can be a male
or female
name”)

Drew Barrymore

Drew Carey

What is the probability of being called
“drew” given that you are a male?

What is the probability
of being a male?

$$p(\text{male} | \text{drew}) = \frac{p(\text{drew} | \text{male}) p(\text{male})}{p(\text{drew})}$$

What is the probability of
being named “drew”?

(actually irrelevant, since it is
that same for all classes)

This is Officer Drew (who arrested me in 1997). Is Officer Drew a **Male** or **Female**?

Luckily, we have a small database with names and gender

Officer Drew

We can use it to apply Bayes rule...

$$p(\text{male} \mid \text{drew}) = \frac{p(\text{drew} \mid \text{male}) p(\text{male})}{p(\text{drew})}$$

$$p(\text{female} \mid \text{drew}) = \frac{p(\text{drew} \mid \text{female}) p(\text{female})}{p(\text{drew})}$$

$$p(c_j \mid d) = \frac{p(d \mid c_j) p(c_j)}{p(d)}$$

| Name | Class |
|---------|--------|
| Drew | Male |
| Claudia | Female |
| Drew | Female |
| Drew | Female |
| Alberto | Male |
| Karin | Female |
| Nina | Female |
| Sergio | Male |

Officer Drew

$$p(\text{male} \mid \text{drew}) = \frac{p(\text{drew} \mid \text{male}) p(\text{male})}{p(\text{drew})}$$

$$= \frac{1/3 * 3/8}{3/8} = \frac{0.125}{3/8}$$

$$p(\text{female} \mid \text{drew}) = \frac{p(\text{drew} \mid \text{female}) p(\text{female})}{p(\text{drew})}$$

$$= \frac{2/5 * 5/8}{3/8} = \frac{0.250}{3/8}$$

| Name | Class |
|---------|--------|
| Drew | Male |
| Claudia | Female |
| Drew | Female |
| Drew | Female |
| Alberto | Male |
| Karin | Female |
| Nina | Female |
| Sergio | Male |

Officer Drew is more likely to be a **Female**.

Officer Drew IS a female!

Officer Drew

$$p(\text{male} | drew) = \frac{1/3 * 3/8}{3/8} = \frac{0.125}{3/8}$$

$$p(\text{female} | drew) = \frac{2/5 * 5/8}{3/8} = \frac{0.250}{3/8}$$

So far we have only considered Bayes Classification when we have one attribute (the “name”). But we may have many features.

How do we use all the features?

$$p(c_j | d) = \frac{p(d | c_j) p(c_j)}{p(d)}$$

| Name | Over 170 CM | Eye | Hair Length | Class |
|---------|-------------|-------|-------------|--------|
| Drew | No | Blue | Short | Male |
| Claudia | Yes | Brown | Long | Female |
| Drew | No | Blue | Long | Female |
| Drew | No | Blue | Long | Female |
| Alberto | Yes | Brown | Short | Male |
| Karin | No | Blue | Long | Female |
| Nina | Yes | Brown | Short | Female |
| Sergio | Yes | Blue | Long | Male |

- To simplify the task, Bayesian classifier assume attributes have independent distributions, and thereby estimate

$$p(d|c_j) = p(d_1|c_j) * p(d_2|c_j) * \dots * p(d_n|c_j)$$

The probability of class c_j generating instance d , equals....

The probability of class c_j generating the observed value for feature 1, multiplied by..

The probability of class c_j generating the observed value for feature 2, multiplied by..

$$P(y|X) = \frac{P(X|y)P(y)}{P(X)}$$

Naïve Bayes
Assumption

$$X = (x_1, x_2, x_3, \dots, x_n)$$

$$P(y|x_1, \dots, x_n) = \frac{P(x_1|y)P(x_2|y)\dots P(x_n|y)P(y)}{P(x_1)P(x_2)\dots P(x_n)}$$

$$P(y|x_1, \dots, x_n) \propto P(y) \prod_{i=1}^n P(x_i|y)$$

$$y = \operatorname{argmax}_y P(y) \prod_{i=1}^n P(x_i|y)$$

Let us take an example to get some better intuition.

- Consider the car theft problem with attributes Color, Type, Origin, and the target,

Stolen can be either Yes or No.

| Example No. | Color | Type | Origin | Stolen? |
|-------------|--------|--------|----------|---------|
| 1 | Red | Sports | Domestic | Yes |
| 2 | Red | Sports | Domestic | No |
| 3 | Red | Sports | Domestic | Yes |
| 4 | Yellow | Sports | Domestic | No |
| 5 | Yellow | Sports | Imported | Yes |
| 6 | Yellow | SUV | Imported | No |
| 7 | Yellow | SUV | Imported | Yes |
| 8 | Yellow | SUV | Domestic | No |
| 9 | Red | SUV | Imported | No |
| 10 | Red | Sports | Imported | Yes |

Consider the car theft problem with attributes Color, Type, Origin, and the target,

Stolen can be either Yes or No.

| Color | Type | Origin | Stolen |
|-------|------|----------|--------|
| Red | SUV | Domestic | ? |

| Example No. | Color | Type | Origin | Stolen? |
|-------------|--------|--------|----------|---------|
| 1 | Red | Sports | Domestic | Yes |
| 2 | Red | Sports | Domestic | No |
| 3 | Red | Sports | Domestic | Yes |
| 4 | Yellow | Sports | Domestic | No |
| 5 | Yellow | Sports | Imported | Yes |
| 6 | Yellow | SUV | Imported | No |
| 7 | Yellow | SUV | Imported | Yes |
| 8 | Yellow | SUV | Domestic | No |
| 9 | Red | SUV | Imported | No |
| 10 | Red | Sports | Imported | Yes |

Frequency and Likelihood tables of 'Color'

Likelihood Table

| | | Stolen? | |
|-------|--------|---------|----|
| | | Yes | No |
| Color | Red | 3 | 2 |
| | Yellow | 2 | 3 |

| | | Stolen? | |
|-------|--------|---------|-------|
| | | P(Yes) | P(No) |
| Color | Red | 3/5 | 2/5 |
| | Yellow | 2/5 | 3/5 |

| Example No. | Color | Type | Origin | Stolen? |
|-------------|--------|--------|----------|---------|
| 1 | Red | Sports | Domestic | Yes |
| 2 | Red | Sports | Domestic | No |
| 3 | Red | Sports | Domestic | Yes |
| 4 | Yellow | Sports | Domestic | No |
| 5 | Yellow | Sports | Imported | Yes |
| 6 | Yellow | SUV | Imported | No |
| 7 | Yellow | SUV | Imported | Yes |
| 8 | Yellow | SUV | Domestic | No |
| 9 | Red | SUV | Imported | No |
| 10 | Red | Sports | Imported | Yes |

Frequency and Likelihood tables of 'Type'

| 9 | Red | SUV | Imported | No |
| 10 | Red | Sports | Imported | Yes |

Frequency and Likelihood tables of 'Origin'

Frequency Table

| | | Stolen? | |
|--------|----------|---------|----|
| | | Yes | No |
| Origin | Domestic | 2 | 3 |
| | Imported | 3 | 2 |

Likelihood Table

| | | Stolen? | |
|--------|----------|---------|-------|
| | | P(Yes) | P(No) |
| Origin | Domestic | 2/5 | 3/5 |
| | Imported | 3/5 | 2/5 |

Likelihood Table

| | | Stolen? | |
|-------|--------|---------|-------|
| | | P(Yes) | P(No) |
| Color | Red | 3/5 | 2/5 |
| | Yellow | 2/5 | 3/5 |

Likelihood Table

| | | Stolen? | |
|------|--------|---------|-------|
| | | P(Yes) | P(No) |
| Type | Sports | 4/5 | 2/5 |
| | SUV | 1/5 | 3/5 |

Likelihood Table

| | | Stolen? | |
|--------|----------|---------|-------|
| | | P(Yes) | P(No) |
| Origin | Domestic | 2/5 | 3/5 |
| | Imported | 3/5 | 2/5 |

Testing part

| Color | Type | Origin | Stolen |
|-------|------|----------|--------|
| Red | SUV | Domestic | ? |

As per the equations discussed above, we can calculate the posterior probability $P(\text{Yes} | X)$ as :

$$\begin{aligned}
 P(\text{Yes} | X) &= P(\text{Red} | \text{Yes}) * P(\text{SUV} | \text{Yes}) * P(\text{Domestic} | \text{Yes}) * P(\text{Yes}) \\
 &= \frac{3}{5} * \frac{1}{5} * \frac{2}{5} * 1 \\
 &= 0.048
 \end{aligned}$$

$P(\text{No} | X)$:

$$\begin{aligned}
 P(\text{No} | X) &= P(\text{Red} | \text{No}) * P(\text{SUV} | \text{No}) * P(\text{Domestic} | \text{No}) * P(\text{No}) \\
 &= \frac{2}{5} * \frac{3}{5} * \frac{3}{5} * 1 \\
 &= 0.144
 \end{aligned}$$

Since $0.144 > 0.048$,

Which means given the features RED SUV and Domestic, our example gets classified as 'NO' the car is not stolen.

Naïve Bayes (NB) Classifier Algorithm

- It is a supervised learning algorithm, which is based on **Bayes theorem** and used for solving classification problems.
- It is mainly used in *text classification* that includes a high-dimensional training dataset.
- Naïve Bayes Classifier is one of the **simple and most effective Classification algorithms** which helps in building the fast machine learning models that can make quick predictions.
- **It is a probabilistic classifier, which means it predicts on the basis of the probability of an object.**
- Some popular examples of Naïve Bayes Algorithm are **spam filtration, Sentimental analysis, and classifying articles.**
- Why is it called Naïve Bayes?
- **Naïve:** It is called Naïve because it assumes that the occurrence of a certain feature is independent of the occurrence of other features.

Such as if the fruit is identified on the bases of color, shape, and taste, then red, spherical, and sweet fruit is recognized as an apple. Hence each feature individually contributes to identify that it is an apple without depending on each other.

- **Bayes:** it depends on the principle of Bayes' Theorem

$$P(y|X) = \frac{P(X|y)P(y)}{P(X)}$$

Naïve Bayes
Assumption

$$X = (x_1, x_2, x_3, \dots, x_n)$$

$$P(y|x_1, \dots, x_n) = \frac{P(x_1|y)P(x_2|y)\dots P(x_n|y)P(y)}{P(x_1)P(x_2)\dots P(x_n)}$$

$$P(y|x_1, \dots, x_n) \propto P(y) \prod_{i=1}^n P(x_i|y)$$

$$y = \operatorname{argmax}_y P(y) \prod_{i=1}^n P(x_i|y)$$

Additional Example

| Whether | Play |
|----------|------|
| Sunny | No |
| Sunny | No |
| Overcast | Yes |
| Rainy | Yes |
| Rainy | Yes |
| Rainy | No |
| Overcast | Yes |
| Sunny | No |
| Sunny | Yes |
| Rainy | Yes |
| Sunny | Yes |
| Overcast | Yes |
| Overcast | Yes |
| Rainy | No |

Frequency Table

| Whether | No | Yes |
|----------|----|-----|
| Overcast | | 4 |
| Sunny | 2 | 3 |
| Rainy | 3 | 2 |
| Total | 5 | 9 |

Likelihood Table 1

| Whether | No | Yes | | |
|----------|---------|---------|---------|------|
| Overcast | | 4 | $=4/14$ | 0.29 |
| Sunny | 2 | 3 | $=5/14$ | 0.36 |
| Rainy | 3 | 2 | $=5/14$ | 0.36 |
| Total | 5 | 9 | | |
| | $=5/14$ | $=9/14$ | | |
| | 0.36 | 0.64 | | |

Likelihood Table 2

| Whether | No | Yes | Posterior Probability for No | Posterior Probability for Yes |
|----------|----|-----|------------------------------|-------------------------------|
| Overcast | | 4 | $0/5=0$ | $4/9=0.44$ |
| Sunny | 2 | 3 | $2/5=0.4$ | $3/9=0.33$ |
| Rainy | 3 | 2 | $3/5=0.6$ | $2/9=0.22$ |
| Total | 5 | 9 | | |

Additional Example

Now suppose you want to calculate the probability of playing when the weather is **overcast**.

Probability of playing:

$$P(\text{Yes} \mid \text{Overcast}) = P(\text{Overcast} \mid \text{Yes}) P(\text{Yes}) / P(\text{Overcast})$$

Calculate Prior Probabilities:

$$P(\text{Overcast}) = 4/14 = 0.29$$

$$P(\text{Yes}) = 9/14 = 0.64$$

Calculate Likelihood Probabilities:

$$P(\text{Overcast} \mid \text{Yes}) = 4/9 = 0.44$$

$$P(\text{Yes} \mid \text{Overcast}) = 0.44 * 0.64 / 0.29 = 0.98 (\text{Higher})$$

Similarly, you can calculate the probability of not playing:

Probability of not playing:

$$P(\text{No} \mid \text{Overcast}) = P(\text{Overcast} \mid \text{No}) P(\text{No}) / P(\text{Overcast})$$

Calculate Prior Probabilities:

$$P(\text{Overcast}) = 4/14 = 0.29$$

$$P(\text{No}) = 5/14 = 0.36$$

Calculate Likelihood Probabilities:

$$P(\text{Overcast} \mid \text{No}) = 0/9 = 0$$

$$P(\text{No} \mid \text{Overcast}) = 0 * 0.36 / 0.29 = 0$$

Likelihood Table 1

| Whether | No | Yes | | |
|----------|-------|-------|-------|------|
| Overcast | | 4 | =4/14 | 0.29 |
| Sunny | 2 | 3 | =5/14 | 0.36 |
| Rainy | 3 | 2 | =5/14 | 0.36 |
| Total | 5 | 9 | | |
| | =5/14 | =9/14 | | |
| | 0.36 | 0.64 | | |

Likelihood Table 2

| Whether | No | Yes | Posterior Probability for No | Posterior Probability for Yes |
|----------|----|-----|------------------------------|-------------------------------|
| Overcast | | 4 | 0/5=0 | 4/9=0.44 |
| Sunny | 2 | 3 | 2/5=0.4 | 3/9=0.33 |
| Rainy | 3 | 2 | 3/5=0.6 | 2/9=0.22 |
| Total | 5 | 9 | | |

The probability of a 'Yes' class is higher. So you can determine here if the weather is overcast than players will play the sport.

Limitation

- **The zero-frequency problem**

Add 1 to the count for every attribute value-class combination (*Laplace estimator*) when an attribute value (Whether=*Overcast*) doesn't occur with every class value (*Play Golf=no*).

An Additional Example

| Whether | Temperature | Play |
|----------|-------------|------|
| Sunny | Hot | No |
| Sunny | Hot | No |
| Overcast | Hot | Yes |
| Rainy | Mild | Yes |
| Rainy | Cool | Yes |
| Rainy | Cool | No |
| Overcast | Cool | Yes |
| Sunny | Mild | No |
| Sunny | Cool | Yes |
| Rainy | Mild | Yes |
| Sunny | Mild | Yes |
| Overcast | Mild | Yes |
| Overcast | Hot | Yes |
| Rainy | Mild | No |

An Additional Example

Now suppose you want to calculate the probability of playing when the weather is overcast, and the temperature is mild.

Probability of playing:

$$P(\text{Play} = \text{Yes} \mid \text{Weather} = \text{Overcast}, \text{Temp} = \text{Mild}) = P(\text{Weather} = \text{Overcast}, \text{Temp} = \text{Mild} \mid \text{Play} = \text{Yes})P(\text{Play} = \text{Yes}) \dots\dots\dots(1)$$

$$P(\text{Weather} = \text{Overcast}, \text{Temp} = \text{Mild} \mid \text{Play} = \text{Yes}) = P(\text{Overcast} \mid \text{Yes}) P(\text{Mild} \mid \text{Yes}) \dots\dots\dots(2)$$

Calculate Prior Probabilities: $P(\text{Yes}) = 9/14 = 0.64$

Calculate likelihood Probabilities: $P(\text{Overcast} \mid \text{Yes}) = 4/9 = 0.44$ $P(\text{Mild} \mid \text{Yes}) = 4/9 = 0.44$

Put Likelihood probabilities in equation (2) $P(\text{Weather} = \text{Overcast}, \text{Temp} = \text{Mild} \mid \text{Play} = \text{Yes}) = 0.44 * 0.44 = 0.1936$ (Higher)

Put Prior and likelihood probabilities in equation (1) $P(\text{Play} = \text{Yes} \mid \text{Weather} = \text{Overcast}, \text{Temp} = \text{Mild}) = 0.1936 * 0.64 = 0.124$

Similarly, you can calculate the probability of not playing:

Probability of not playing:

$$P(\text{Play} = \text{No} \mid \text{Weather} = \text{Overcast}, \text{Temp} = \text{Mild}) = P(\text{Weather} = \text{Overcast}, \text{Temp} = \text{Mild} \mid \text{Play} = \text{No})P(\text{Play} = \text{No}) \dots\dots\dots(3)$$

$$P(\text{Weather} = \text{Overcast}, \text{Temp} = \text{Mild} \mid \text{Play} = \text{No}) = P(\text{Weather} = \text{Overcast} \mid \text{Play} = \text{No}) P(\text{Temp} = \text{Mild} \mid \text{Play} = \text{No}) \dots\dots\dots(4)$$

Calculate Prior Probabilities: $P(\text{No}) = 5/14 = 0.36$

Calculate likelihood Probabilities: $P(\text{Weather} = \text{Overcast} \mid \text{Play} = \text{No}) = 0/9 = 0$ $P(\text{Temp} = \text{Mild} \mid \text{Play} = \text{No}) = 2/5 = 0.4$

Put posterior probabilities in equation (4) $P(\text{Weather} = \text{Overcast}, \text{Temp} = \text{Mild} \mid \text{Play} = \text{No}) = 0 * 0.4 = 0$

Put prior and posterior probabilities in equation (3) $P(\text{Play} = \text{No} \mid \text{Weather} = \text{Overcast}, \text{Temp} = \text{Mild}) = 0 * 0.36 = 0$

The probability of a 'Yes' class is higher. So you can say here that if the weather is overcast then players will play the sport.

Example

| Outlook | Temp | Humidity | Windy | Play Golf |
|----------|------|----------|-------|-----------|
| Rainy | Hot | High | False | No |
| Rainy | Hot | High | True | No |
| Overcast | Hot | High | False | Yes |
| Sunny | Mild | High | False | Yes |
| Sunny | Cool | Normal | False | Yes |
| Sunny | Cool | Normal | True | No |
| Overcast | Cool | Normal | True | Yes |
| Rainy | Mild | High | False | No |
| Rainy | Cool | Normal | False | Yes |
| Sunny | Mild | Normal | False | Yes |
| Rainy | Mild | Normal | True | Yes |
| Overcast | Mild | High | True | Yes |
| Overcast | Hot | Normal | False | Yes |
| Sunny | Mild | High | True | No |

- The posterior probability can be calculated by first, constructing a frequency table for each attribute against the target.
- Then, transforming the frequency tables to likelihood tables and finally use the Naive Bayesian equation to calculate the posterior probability for each class.
- The class with the highest posterior probability is the outcome of prediction.

$$P(x | c) = P(\text{Sunny} | \text{Yes}) = 3 / 9 = 0.33$$

| Frequency Table | | Play Golf | |
|-----------------|----------|-----------|----|
| | | Yes | No |
| Outlook | Sunny | 3 | 2 |
| | Overcast | 4 | 0 |
| | Rainy | 2 | 3 |

| Likelihood Table | | Play Golf | | |
|------------------|----------|-----------|------|------|
| | | Yes | No | |
| Outlook | Sunny | 3/9 | 2/5 | 5/14 |
| | Overcast | 4/9 | 0/5 | 4/14 |
| | Rainy | 2/9 | 3/5 | 5/14 |
| | | 9/14 | 5/14 | |

$$P(x) = P(\text{Sunny}) = 5 / 14 = 0.36$$

$$P(c) = P(\text{Yes}) = 9 / 14 = 0.64$$

Posterior Probability:

$$P(c | x) = P(\text{Yes} | \text{Sunny}) = 0.33 \times 0.64 \div 0.36 = 0.60$$

$$P(x | c) = P(\text{Sunny} | \text{No}) = 2 / 5 = 0.4$$

| Frequency Table | | Play Golf | |
|-----------------|----------|-----------|----|
| | | Yes | No |
| Outlook | Sunny | 3 | 2 |
| | Overcast | 4 | 0 |
| | Rainy | 2 | 3 |

| | | Play Golf | | |
|---------|----------|-----------|----|----|
| | | Yes | No | |
| Outlook | Sunny | 3 | 2 | 5 |
| | Overcast | 4 | 0 | 4 |
| | Rainy | 2 | 3 | 5 |
| | | 9 | 5 | 14 |

$$P(x) = P(\text{Sunny}) = 5 / 14 = 0.36$$

$$P(c) = P(\text{No}) = 5 / 14 = 0.36$$

Posterior Probability:

$$P(c | x) = P(\text{No} | \text{Sunny}) = 0.40 \times 0.36 \div 0.36 = 0.40$$

Frequency Table

| | | Play Golf | |
|---------|----------|-----------|----|
| | | Yes | No |
| Outlook | Sunny | 3 | 2 |
| | Overcast | 4 | 0 |
| | Rainy | 2 | 3 |

| | | Yes | No |
| Windy | False | 6 | 2 |
| | True | 3 | 3 |

Likelihood Table

| | | Play Golf | |
|---------|----------|-----------|-----|
| | | Yes | No |
| Outlook | Sunny | 3/9 | 2/5 |
| | Overcast | 4/9 | 0/5 |
| | Rainy | 2/9 | 3/5 |

| | | Play Golf | |
|----------|--------|-----------|-----|
| | | Yes | No |
| Humidity | High | 3/9 | 4/5 |
| | Normal | 6/9 | 1/5 |

| | | Play Golf | |
|-------|------|-----------|-----|
| | | Yes | No |
| Temp. | Hot | 2/9 | 2/5 |
| | Mild | 4/9 | 2/5 |
| | Cool | 3/9 | 1/5 |

| | | Play Golf | |
|-------|-------|-----------|-----|
| | | Yes | No |
| Windy | False | 6/9 | 2/5 |
| | True | 3/9 | 3/5 |

| Outlook | Temp | Humidity | Windy | Play |
|---------|------|----------|-------|------|
| Rainy | Cool | High | True | ? |

$$P(Yes | X) = P(Rainy | Yes) \times P(Cool | Yes) \times P(High | Yes) \times P(True | Yes) \times P(Yes)$$

$$P(Yes | X) = 2/9 \times 3/9 \times 3/9 \times 3/9 \times 9/14 = 0.00529 \rightarrow 0.2 = \frac{0.00529}{0.02057 + 0.00529}$$

$$P(No | X) = P(Rainy | No) \times P(Cool | No) \times P(High | No) \times P(True | No) \times P(No)$$

$$P(No | X) = 3/5 \times 1/5 \times 4/5 \times 3/5 \times 5/14 = 0.02057 \rightarrow 0.8 = \frac{0.02057}{0.02057 + 0.00529}$$

More example

- Let's consider a simple dataset comprised of 10 data samples:

Example

| Type of family structure | Age group | Income status | Will they buy a car? |
|--------------------------|-------------|---------------|----------------------|
| Nuclear | Young | Low | Yes |
| Extended | Old | Low | No |
| Childless | Middle-aged | Low | No |
| Childless | Young | Medium | Yes |
| Single Parent | Middle-aged | Medium | Yes |
| Childless | Young | Low | No |
| Nuclear | Old | High | Yes |
| Nuclear | Middle-aged | Medium | Yes |
| Extended | Middle-aged | High | Yes |
| Single Parent | Old | Low | No |

Given three inputs—for example, Single Parent, Young, and Low—we want to compute the probability of these people buying a car. Let's use Naive Bayes.

Firstly, let's compute the probability of the output labels ($P(Y)$) given the data.

$$P(\text{No}) = 4/10$$

$$P(\text{Yes}) = 6/10$$

Now let's calculate the probability of the likelihood of the evidence. Given the inputs Childless, Young, and Low, we'll calculate the probability with respect to both class labels as follows:

$$P(\text{Single Parent}|\text{Yes}) = 1/6$$

$$P(\text{Single Parent}|\text{No}) = 1/4$$

$$P(\text{Young}|\text{Yes}) = 2/6$$

$$P(\text{Young}|\text{No}) = 1/4$$

$$P(\text{Low}|\text{Yes}) = 1/6$$

$$P(\text{Low}|\text{No}) = 4/4$$

Since $P(X_1) * P(X_2) * \dots * P(X_n)$ remains the same when calculating the probability for both Yes and No output labels, we can eliminate that value.

Thus, the posterior probability is computed as follows (note that X is the test data):

$$P(\text{Yes}|X) = P(\text{Single Parent}|\text{Yes}) * P(\text{Young}|\text{Yes}) * P(\text{Low}|\text{Yes}) = 1/6 * 2/6 * 1/6 = 0.0063$$

$$P(\text{No}|X) = P(\text{Single Parent}|\text{No}) * P(\text{Young}|\text{No}) * P(\text{Low}|\text{No}) = 1/4 * 1/4 * 4/4 = 0.0625$$

The final probabilities are:

$$P(\text{Yes}|X) = 0.0063 / (0.0063 + 0.0625) = 0.09$$

$$P(\text{No}|X) = 0.0625 / (0.0063 + 0.0625) = 0.91$$

Thus, the results clearly show that the car probably will not be purchased.

We previously mentioned that the "naiveness" of the algorithm is that it assumes each feature is independent of the others. We calculated the probabilities with respect to the output label with this assumption, so that each feature has an equal contribution and is independent of all the other features.

Let's take a dataset to predict whether we can *pet an animal or not*.

| | Animals | Size of Animal | Body Color | Can we Pet them |
|----|---------|----------------|------------|-----------------|
| 0 | Dog | Medium | Black | Yes |
| 1 | Dog | Big | White | No |
| 2 | Rat | Small | White | Yes |
| 3 | Cow | Big | White | Yes |
| 4 | Cow | Small | Brown | No |
| 5 | Cow | Big | Black | Yes |
| 6 | Rat | Big | Brown | No |
| 7 | Dog | Small | Brown | Yes |
| 8 | Dog | Medium | Brown | Yes |
| 9 | Cow | Medium | White | No |
| 10 | Dog | Small | Black | Yes |
| 11 | Rat | Medium | Black | No |
| 12 | Rat | Small | Brown | No |
| 13 | Cow | Big | White | Yes |

Now if we send our test data, suppose **test**
= (Cow, Medium, Black)

Animals

| | Yes | No | P(Yes) | P(No) |
|--------------|-----|----|--------|-------|
| Dog | 4 | 1 | 4/8 | 1/6 |
| Rat | 1 | 3 | 1/8 | 3/6 |
| Cow | 3 | 2 | 3/8 | 2/6 |
| Total | 8 | 6 | 100% | 100% |

Size of Animal

| | Yes | No | P(Yes) | P(No) |
|--------------|-----|----|--------|-------|
| Medium | 2 | 2 | 2/8 | 2/6 |
| Big | 3 | 2 | 3/8 | 2/6 |
| Small | 3 | 2 | 3/8 | 2/6 |
| Total | 8 | 6 | 100% | 100% |

Body Color

| | Yes | No | P(Yes) | P(No) |
|--------------|-----|----|--------|-------|
| Black | 3 | 1 | 3/8 | 1/6 |
| White | 3 | 2 | 3/8 | 2/6 |
| Brown | 2 | 3 | 2/8 | 3/6 |
| Total | 8 | 6 | 100% | 100% |

Now if we send our test data, suppose **test**
= (Cow, Medium, Black)

Probability of petting an animal :

$$P(Yes|Test) = \frac{P(Animal = Cow|Yes) * P(Size = Medium|Yes) * P(Color = Black|Yes) * P(Yes)}{P(Test)}$$

$$P(Yes|Test) = \frac{3}{8} * \frac{2}{8} * \frac{3}{8} * \frac{8}{14} = 0.0200$$

And the probability of not petting an animal:

$$P(No|Test) = \frac{P(Animal = Cow|No) * P(Size = Medium|No) * P(Color = Black|No) * P(No)}{P(Test)}$$

$$P(No|Test) = \frac{2}{6} * \frac{2}{6} * \frac{1}{6} * \frac{6}{14} = 0.0079$$

We see here that $P(Yes|Test) > P(No|Test)$, so the prediction that we can pet this animal is **“Yes”**.

Numerical Predictors

Numerical variables need to be transformed to their categorical counterparts ([binning](#)) before constructing their frequency tables.

The other option we have is using the distribution of the numerical variable to have a good guess of the frequency. For example, one common practice is to assume **normal distributions** for numerical variables. The probability density function for the normal distribution is defined by two parameters (mean and standard deviation).

$$\mu = \frac{1}{n} \sum_{i=1}^n x_i$$

Mean

$$\sigma = \left[\frac{1}{n-1} \sum_{i=1}^n (x_i - \mu)^2 \right]^{0.5}$$

Standard deviation

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

Normal distribution

$$P(\text{humidity} = 74 \mid \text{play} = \text{yes}) = \frac{1}{\sqrt{2\pi}(10.2)} e^{-\frac{(74-79.1)^2}{2(10.2)^2}} = 0.0344$$

$$P(\text{humidity} = 74 \mid \text{play} = \text{no}) = \frac{1}{\sqrt{2\pi}(9.7)} e^{-\frac{(74-86.2)^2}{2(9.7)^2}} = 0.0187$$

| | | Humidity | | | | | | | | | | Mean | StDev |
|--------------|-----|----------|----|----|----|----|----|----|----|----|--|------|-------|
| Play Golf | yes | 86 | 96 | 80 | 65 | 70 | 80 | 70 | 90 | 75 | | 79.1 | 10.2 |
| | no | 85 | 90 | 70 | 95 | 91 | | | | | | 86.2 | 9.7 |

Numerical Value Example

- Problem: classify whether a given person is a male or a female based on the measured features.
- The features include height, weight, and foot size.
- Although with NB classifier we treat them as independent, they are not in reality.

| Person | height (feet) | weight (lbs) | foot size(inches) |
|--------|---------------|--------------|-------------------|
| male | 6 | 180 | 12 |
| male | 5.92 (5'11") | 190 | 11 |
| male | 5.58 (5'7") | 170 | 12 |
| male | 5.92 (5'11") | 165 | 10 |
| female | 5 | 100 | 6 |
| female | 5.5 (5'6") | 150 | 8 |
| female | 5.42 (5'5") | 130 | 7 |
| Female | 5.75 (5'9") | 150 | 9 |

The classifier created from the training set using a Gaussian distribution assumption

| Person | mean (height) | variance (height) | mean (weight) | variance (weight) | mean (foot size) | variance (foot size) |
|--------|---------------|-------------------------|---------------|----------------------|------------------|-------------------------|
| male | 5.855 | 3.5033×10^{-2} | 176.25 | 1.2292×10^2 | 11.25 | 9.1667×10^{-1} |
| female | 5.4175 | 9.7225×10^{-2} | 132.5 | 5.5833×10^2 | 7.5 | 1.6667 |

Below is a sample to be classified as male or female.

| Person | height (feet) | weight (lbs) | foot size(inches) |
|--------|---------------|--------------|-------------------|
| sample | 6 | 130 | 8 |

In order to classify the sample, one has to determine which posterior is greater, male or female. For the classification as male the posterior is given by

In order to classify the sample, one has to determine which posterior is greater, male or female. For the classification as male the posterior is given by

$$\text{posterior (male)} = \frac{P(\text{male})p(\text{height} \mid \text{male})p(\text{weight} \mid \text{male})p(\text{foot size} \mid \text{male})}{\text{evidence}}$$

For the classification as female the posterior is given by

$$\text{posterior (female)} = \frac{P(\text{female})p(\text{height} \mid \text{female})p(\text{weight} \mid \text{female})p(\text{foot size} \mid \text{female})}{\text{evidence}}$$

$$P(\text{male}) = 0.5$$

$$p(\text{height} \mid \text{male}) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(\frac{-(6 - \mu)^2}{2\sigma^2}\right) \approx 1.5789,$$

where $\mu = 5.855$ and $\sigma^2 = 3.5033 \cdot 10^{-2}$ are the parameters of normal distribution which have been previously determined from the training set.

$$p(\text{weight} \mid \text{male}) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(\frac{-(130 - \mu)^2}{2\sigma^2}\right) = 5.9881 \cdot 10^{-6}$$

$$p(\text{foot size} \mid \text{male}) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(\frac{-(8 - \mu)^2}{2\sigma^2}\right) = 1.3112 \cdot 10^{-3}$$

$$\text{posterior numerator (male)} = \text{their product} = 6.1984 \cdot 10^{-9}$$

$$P(\text{female}) = 0.5$$

$$p(\text{height} \mid \text{female}) = 2.23 \cdot 10^{-1}$$

$$p(\text{weight} \mid \text{female}) = 1.6789 \cdot 10^{-2}$$

$$p(\text{foot size} \mid \text{female}) = 2.8669 \cdot 10^{-1}$$

$$\text{posterior numerator (female)} = \text{their product} = 5.3778 \cdot 10^{-4}$$

Since posterior numerator is greater in the female case, the prediction is that the sample is female.

E-mail Filtering Problem

Example — Let us understand this with an example of email classification as spam or ham (i.e. no spam).

We simply count the number of words in both classes of email and then find the probability of each word's probability given the class prior probability of that email as spam or ham.

And then using the Naive Bayes, assuming that the occurrence of each word is independent of each other, we calculate the probability of a new email containing the words 'friend', 'rich', 'beach', 'money'.

Total emails: 72

Prob. Ham
= 72/100
= 0.72

Prob. Spam
= 28/100
= 0.28

Total emails : 28

| Word | Count | Prob of Word if mail is Ham |
|--------|-------|-----------------------------|
| Friend | 86 | 0.238227 |
| Rich | 41 | 0.113573 |
| Money | 79 | 0.218837 |
| Beach | 80 | 0.221607 |
| Office | 75 | 0.207756 |

Ham: Total words=361

| Word | Count | Prob of Word if mail is Spam |
|--------|-------|------------------------------|
| Friend | 63 | 0.184751 |
| Rich | 36 | 0.105572 |
| Money | 97 | 0.284457 |
| Beach | 53 | 0.155425 |
| Office | 92 | 0.269795 |

Spam: Total words=341

Probability new email is Ham

$$P(H) \times P(\text{Friend}|H) \times P(\text{Rich}|H) \times P(\text{Beach}|H) \times P(\text{Money}|H)$$

Probability new email is Spam

$$P(S) \times P(\text{Friend}|S) \times P(\text{Rich}|S) \times P(\text{Beach}|S) \times P(\text{Money}|S)$$

The Zero frequency problem:

Total emails: 72

Total emails : 28

Prob. Ham
= 72/100
= 0.72

Prob. Spam
= 28/100
= 0.28

HAM Total Words 263

| Word | Count | Prob of Word if mail is Ham |
|--------|-------|-----------------------------|
| Friend | 86 | 0.326996 |
| Rich | 3 | 0.011407 |
| Money | 9 | 0.034221 |
| Beach | 90 | 0.342205 |
| Office | 75 | 0.285171 |

SPAM Total Words 243

| Word | Count | Prob of Word if mail is Spam |
|--------|-------|------------------------------|
| Friend | 59 | 0.242798 |
| Rich | 63 | 0.259259 |
| Money | 97 | 0.399177 |
| Beach | 24 | 0.098765 |
| Office | 0 | 0 |

Probability new email is Ham

$$P(\text{H}) \times P(\text{Office} | \text{H}) \times P(\text{Rich} | \text{H}) \times P(\text{Rich} | \text{H}) \times P(\text{Money} | \text{H})$$

$$0.72 \times 0.28 \times 0.01 \times 0.01 \times 0.03 = \mathbf{0.00000091}$$

Probability new email is Spam

$$P(\text{S}) \times P(\text{Office} | \text{S}) \times P(\text{Rich} | \text{S}) \times P(\text{Rich} | \text{S}) \times P(\text{Money} | \text{S})$$

$$0.28 \times \mathbf{0} \times 0.24 \times 0.24 \times 0.37 = \mathbf{0.0}$$

HAM??

The Zero frequency problem:

Total emails: 72

Total emails : 28

$$\begin{aligned}\text{Prob. Ham} &= 72/100 \\ &= 0.72\end{aligned}$$

$$\begin{aligned}\text{Prob. Spam} &= 28/100 \\ &= 0.28\end{aligned}$$

| HAM Total Words 268 | | | |
|------------------------|-------|-----------|-----------------------------|
| Word | Count | Count New | Prob of Word if mail is Ham |
| Friend | 86 +1 | 87 | 0.324627 |
| Rich | 3 +1 | 4 | 0.014925 |
| Money | 9 +1 | 10 | 0.037313 |
| Beach | 90 +1 | 91 | 0.339552 |
| Office | 75 +1 | 76 | 0.283582 |

| SPAM Total Words 248 | | | |
|-------------------------|-------|-----------|------------------------------|
| Word | Count | Count New | Prob of Word if mail is Spam |
| Friend | 59 +1 | 60 | 0.241935 |
| Rich | 63 +1 | 64 | 0.258065 |
| Money | 97 +1 | 98 | 0.395161 |
| Beach | 24 +1 | 25 | 0.100806 |
| Office | 0 +1 | 1 | 0.004032 |

Probability new email is Ham

$$P(\text{H}) \times P(\text{Office}|\text{H}) \times P(\text{Rich}|\text{H}) \times P(\text{Rich}|\text{H}) \times P(\text{Money}|\text{H})$$

$$0.72 \times 0.28 \times 0.01 \times 0.01 \times 0.04 = \mathbf{0.0000017}$$

Probability new email is Spam

$$P(\text{S}) \times P(\text{Office}|\text{S}) \times P(\text{Rich}|\text{S}) \times P(\text{Rich}|\text{S}) \times P(\text{Money}|\text{S})$$

$$0.28 \times 0.004 \times 0.25 \times 0.25 \times 0.39 = \mathbf{0.000029}$$

SPAM!!!

Suppose we are building a classifier that says whether a text is about sports or not. Our training data has 5 sentences:

| Text | Tag |
|--------------------------------|------------|
| "A great game" | Sports |
| "The election was over" | Not sports |
| "Very clean match" | Sports |
| "A clean but forgettable game" | Sports |
| "It was a close election" | Not sports |

Now, which tag does the sentence *A very close game* belong to?

| Text | Tag |
|--------------------------------|------------|
| "A great game" | Sports |
| "The election was over" | Not sports |
| "Very clean match" | Sports |
| "A clean but forgettable game" | Sports |
| "It was a close election" | Not sports |

['a', 'great', 'very', 'over', 'it', 'but', 'game', 'election', 'clean', 'close', 'the', 'was', 'forgettable', 'match'].

$$P(sports|a\ very\ close\ game) = \frac{P(a\ very\ close\ game|sports) \times P(sports)}{P(a\ very\ close\ game)}$$

$$P(a\ very\ close\ game|Sports) = P(a|Sports) \times P(very|Sports) \times P(close|Sports) \times P(game|Sports)$$

$$P(game|Sports) = \frac{2}{11}$$

$$P(a|Sports) \times P(very|Sports) \times 0 \times P(game|Sports)$$

$$P(game|sports) = \frac{2 + 1}{11 + 14}$$

| Text | Tag |
|--------------------------------|------------|
| "A great game" | Sports |
| "The election was over" | Not sports |
| "Very clean match" | Sports |
| "A clean but forgettable game" | Sports |
| "It was a close election" | Not sports |

| Word | P (word Sports) | P (word Not Sports) |
|-------|--------------------------|-------------------------|
| a | $(2 + 1) \div (11 + 14)$ | $(1 + 1) \div (9 + 14)$ |
| very | $(1 + 1) \div (11 + 14)$ | $(0 + 1) \div (9 + 14)$ |
| close | $(0 + 1) \div (11 + 14)$ | $(1 + 1) \div (9 + 14)$ |
| game | $(2 + 1) \div (11 + 14)$ | $(0 + 1) \div (9 + 14)$ |

Now we just multiply all the probabilities, and see who is bigger:

$$\begin{aligned}
 &P(a|Sports) \times P(very|Sports) \times P(close|Sports) \times P(game|Sports) \times \\
 &P(Sports) \\
 &= 2.76 \times 10^{-5} \\
 &= 0.0000276
 \end{aligned}$$

$$\begin{aligned}
 &P(a|Not Sports) \times P(very|Not Sports) \times P(close|Not Sports) \times P(game|Not Sports) \times \\
 &P(Not Sports) \\
 &= 0.572 \times 10^{-5} \\
 &= 0.00000572
 \end{aligned}$$

Excellent! Our classifier gives "A very close game" the **Sports** tag.

Build a NB classifier for predicting a class category (either + or -)

Table 1: The training and testing datasets for Question 5.

| | Cat | Documents |
|----------|-----|---------------------------------------|
| Training | - | just plain boring |
| | - | entirely predictable and lacks energy |
| | - | no surprises and very few laughs |
| | + | very powerful |
| | + | the most fun film of the summer |
| Test | ? | predictable with no fun |

Naive Bayes

Advantages of Naive Bayes

- This algorithm works **very fast and can easily predict the class** of a test dataset.
- You can use it to solve **multi-class prediction problems** as it's quite useful with them.
- Naive Bayes classifier performs better than other models with less training data if the assumption of independence of features holds.
- If you have categorical input variables, the Naive Bayes algorithm performs exceptionally well in comparison to numerical variables.
- It can be used for Binary and Multi-class Classifications.
- It effectively works in Multi-class predictions.

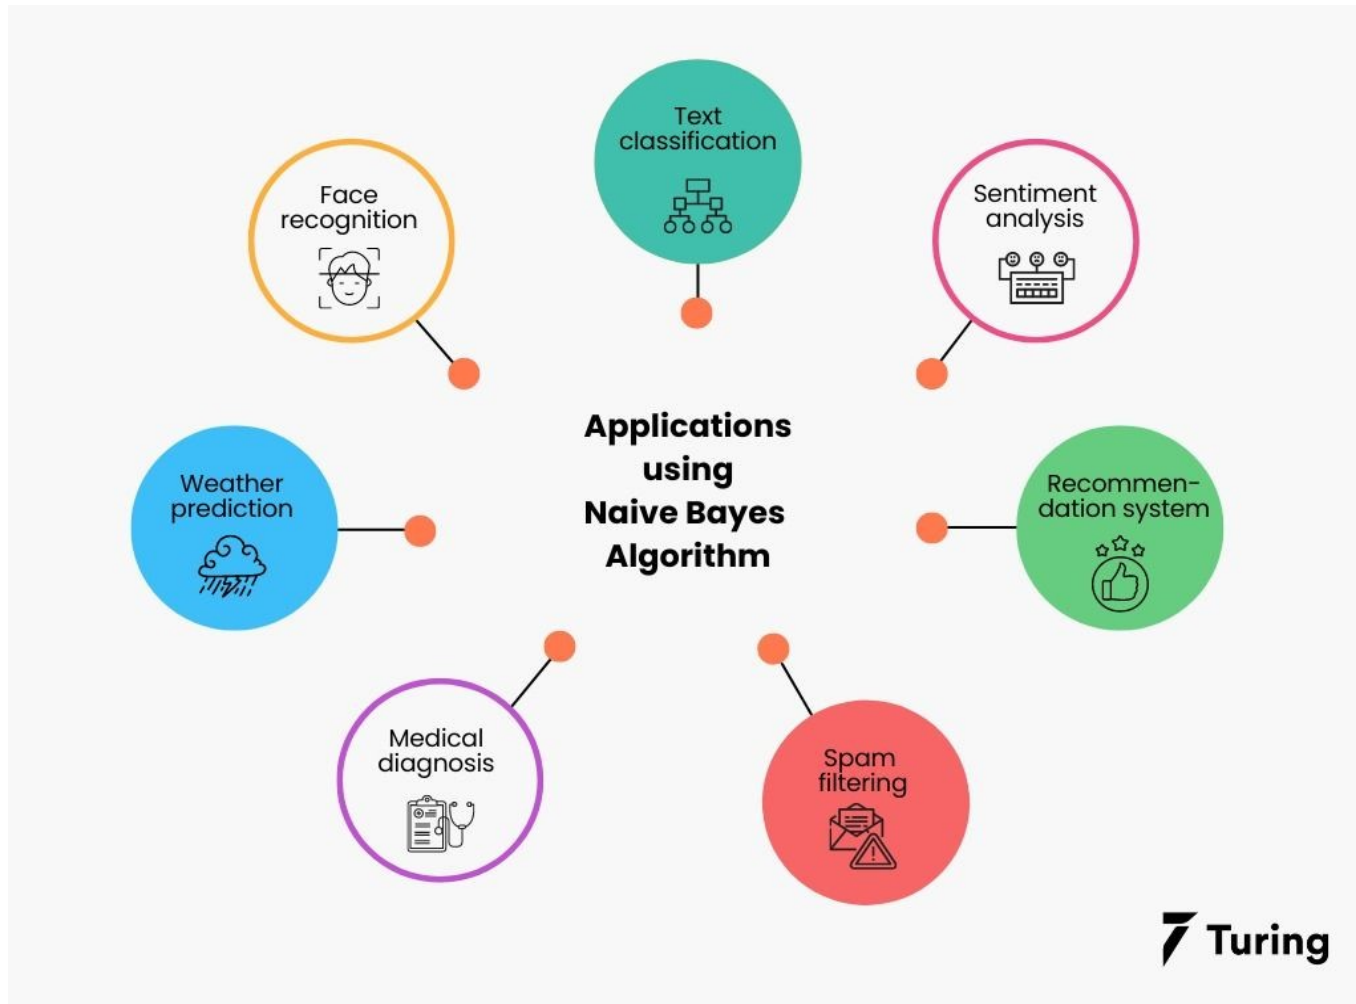

Disadvantages of Naive Bayes

- If your test data set has a categorical variable of a category that wasn't present in the training data set, the Naive Bayes model will assign it **zero probability** and won't be able to make any predictions in this regard. This phenomenon is called 'Zero Frequency,' and you'll have to use a smoothing technique to solve this problem.
- It assumes that all the features are independent. While it might sound great in theory, in real life, you'll hardly find a set of independent features.

Applications

- **Real-time prediction:** Naive Bayes is an eager learning classifier and is quite fast in its execution. Thus, it could be used for making predictions in real-time.
- **Multi-class prediction:** The Naive Bayes algorithm is also well-known for multi-class prediction, or classifying instances into one of several different classes.
- **Text classification/spam filtering/sentiment analysis:** When used to classify text, a Naive Bayes classifier often achieves a higher success rate than other algorithms due to its ability to perform well on multi-class problems while assuming independence. As a result, it is widely used in spam filtering (identifying spam email) and sentiment analysis (e.g. in social media, to identify positive and negative customer sentiments).
- **Recommendation Systems:** A Naive Bayes Classifier can be used together with Collaborative Filtering to build a Recommendation System which could filter through new information and predict whether a user would like a given resource or not.

Applications

Types of Naive Bayes classifier?

The main types of Naive Bayes classifier are mentioned below:

- **Multinomial Naive Bayes** — These types of classifiers are usually used for the problems of document classification. It checks whether the document belongs to a particular category like sports or technology or political etc and then classifies them accordingly. The predictors used for classification in this technique are the frequency of words present in the document.
- **Bernoulli Naive Bayes** — This classifier is also analogous to multinomial naive bayes but instead of words, the predictors are Boolean values. The parameters used to predict the class variable accepts only yes or no values, for example, if a word occurs in the text or not.
- **Gaussian Naive Bayes** — In a Gaussian Naive Bayes, the predictors take a continuous value assuming that it has been sampled from a Gaussian Distribution. It is also called a Normal Distribution.

How to Find Accuracy of Classifier?

Example of Classifier

Total are 12= 8 (with cancer) + 4 (without cancer)

Encoding: cancer (Positive- class 1), cancer-free (negative- class 0)

| Individual Number | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
|-----------------------|---|---|---|---|---|---|---|---|---|----|----|----|
| Actual Classification | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 |

| Individual Number | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
|--------------------------|---|---|---|---|---|---|---|---|---|----|----|----|

Confusion Matrix

| | | Predicted condition | |
|-----------------------------|--------------|---------------------|---------------------|
| Total population = P + N | | Positive (PP) | Negative (PN) |
| Actual condition | Positive (P) | True positive (TP) | False negative (FN) |
| | Negative (N) | False positive (FP) | True negative (TN) |

| | | Predicted condition | |
|---------------------|-----------------|---------------------|------------|
| Total 8 + 4 = 12 | | Cancer | Non-cancer |
| Actual condition | Cancer 8 | 6 | 2 |
| | Non-cancer 4 | 1 | 3 |

$$\text{Precision} = \frac{\text{True Positive}}{\text{True Positive} + \text{False Positive}}$$

$$= \frac{\text{True Positive}}{\text{Total Predicted Positive}}$$

$$\text{Recall} = \frac{\text{True Positive}}{\text{True Positive} + \text{False Negative}}$$

$$= \frac{\text{True Positive}}{\text{Total Actual Positive}}$$

“Out of all the data points that should be predicted as true, how many did we correctly predict as true?”

$$F1 = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$$

F1 can therefore be used to measure how effectively our models make that trade-off among Precision and Recall

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN}$$

“Out of all the positive predictions we made, how many were true?”

| | | Predicted condition | |
|------------------|-----------------------------|---------------------|---------------------|
| | | Positive (PP) | Negative (PN) |
| Actual condition | Total population = P + N | | |
| | Positive (P) | True positive (TP) | False negative (FN) |
| | Negative (N) | False positive (FP) | True negative (TN) |

| | | Predicted condition | |
|------------------|---------------------|---------------------|------------|
| | | Cancer | Non-cancer |
| Actual condition | Total 8 + 4 = 12 | 7 | 5 |
| | Cancer 8 | 6 | 2 |
| | Non-cancer 4 | 1 | 3 |

Example-1

Problem: Email spam filtering

Total sample: 100

Accuracy =70%

Precision=TP/(TP+FP)=10/30=33%

Confusion Matrix

| | | Predicted condition | |
|------------------|-----------------------------|---------------------|---------------|
| | | Positive (PP) | Negative (PN) |
| Actual condition | Total population = P + N | | |
| | Positive (P) | TP=10 | FN=10 |
| | Negative (N) | FP=20 | TN=60 |

Example-2

Problem: Tumor as cancerous or noncancerous

Total sample: 2000

Accuracy =70%

Recall=TP/(TP+FN)=200/600=33%

Confusion Matrix

| | | Predicted condition | |
|------------------|-----------------------------|---------------------|---------------|
| | | Positive (PP) | Negative (PN) |
| Actual condition | Total population = P + N | | |
| | Positive (P) | TP=200 | FN=400 |
| | Negative (N) | FP=200 | TN=1200 |

Example-3

Problem: Tumor as cancerous or noncancerous

Total sample: 2000

Accuracy =35%

Recall=TP/(TP+FN)=200/250=80%

Confusion Matrix

| | | Predicted condition | |
|------------------|-----------------------------|---------------------|---------------|
| | | Positive (PP) | Negative (PN) |
| Actual condition | Total population = P + N | | |
| | Positive (P) | TP=200 | FN=50 |
| | Negative (N) | FP=1250 | TN=500 |

Summary of Strength and Weakness of Metrics

| Metrics | Strengths | Weaknesses |
|------------------|---|---|
| Accuracy | Easy to understand and compute; provides a general performance measure. | It can be misleading in imbalanced datasets and does not differentiate between types of errors. |
| Precision | Useful when the cost of false positives is high; measures the accuracy of positive predictions. | It does not account for false negatives and can be less informative if not considered with recall. |
| Recall | Crucial when the cost of false negatives is high; it measures the ability to identify positive instances. | It does not account for false positives and can be less informative if not considered with precision. |
| F1 Score | Balances precision and recall; useful in imbalanced datasets. | It does not account for true negative rates |
